# **UML Class Diagram Tutorial**

#### **Class Notation**

A class notation consists of three parts:

### 1. Class Name

• The name of the class appears in the first partition.

### 2. Class Attributes

- Attributes are shown in the second partition.
- The attribute type is shown after the colon.
- Attributes map onto member variables (data members) in code.

### 3. Class Operations (Methods)

- Operations are shown in the third partition. They are services the class provides.
- The return type of a method is shown after the colon at the end of the method signature.
- The return type of method parameters are shown after the colon following the parameter name.
- Operations map onto class methods in code

MyClass

+attribute1 : int
-attribute2 : float
#attribute3 : Circle

+op1(in p1 : bool, in p2) : String
-op2(input p3 : int) : float
#op3(out p6) : Class6\*

The graphical representation of the class - MyClass as shown above:

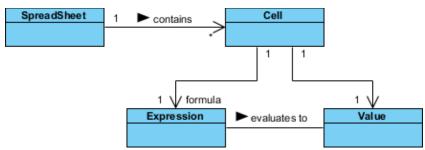

- MyClass has 3 attributes and 3 operations
- Parameter p3 of op2 is of type int
- op2 returns a float
- op3 returns a pointer (denoted by a \*) to Class6

### **Class Relationships**

A class may be involved in one or more relationships with other classes. A relationship can be one of the following types: (Refer to the figure on the right for the graphical representation of relationships).

# **Inheritance** (or Generalization): • Represents an "is-a" relationship. SuperClass • An abstract class name is shown in italics. • SubClass1 and SubClass2 are specializations of Super Class. A solid line with a hollow arrowhead that point from the child to the parent class Subclass1 Subclass2 Simple Association: Class2 • A structural link between two peer classes. Class1 • There is an association between Class1 and Class2 A solid line connecting two classes Aggregation: A special type of association. It represents a "part of" Class1 Class2 relationship. Class2 is part of Class1. • Many instances (denoted by the \*) of Class2 can be associated with Class1. • Objects of Class1 and Class2 have separate lifetimes. A solid line with a unfilled diamond at the association end connected to the class of composite Composition: A special type of aggregation where parts are destroyed Class1 Class2 when the whole is destroyed. Objects of Class2 live and die with Class1. Class2 cannot stand by itself. A solid line with a filled diamond at the association connected to the class of composite Dependency: Exists between two classes if changes to the Class1 Class2 definition of one may cause changes to the other (but not the other way around). • Class1 depends on Class2 A dashed line with an open arrow

## **Navigability**

The arrows indicate whether, given one instance participating in a relationship, it is possible to determine the instances of the other class that are related to it.

The diagram above suggests that,

- Given a spreadsheet, we can locate all of the cells that it contains, but that
  - we cannot determine from a cell in what spreadsheet it is contained.
- Given a cell, we can obtain the related expression and value, but
  - given a value (or expression) we cannot find the cell of which those are attributes.

# **Visibility of Class attributes and Operations**

In object-oriented design, there is a notation of visibility for attributes and operations. UML identifies four types of visibility: **public**, **protected**, **private**, and **package**.

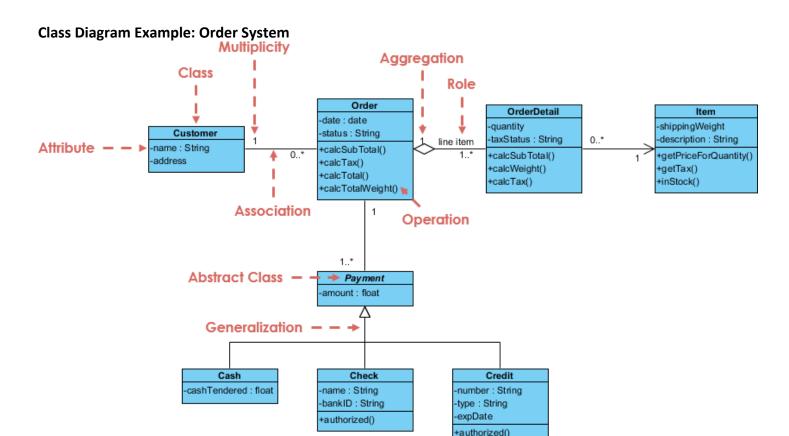

The +, -, # and ~ symbols before an attribute and operation name in a class denote the visibility of the attribute and operation.

- + denotes public attributes or operations
- denotes private attributes or operations
- # denotes protected attributes or operations
- ~ denotes package attributes or operations

## **Class Visibility Example**

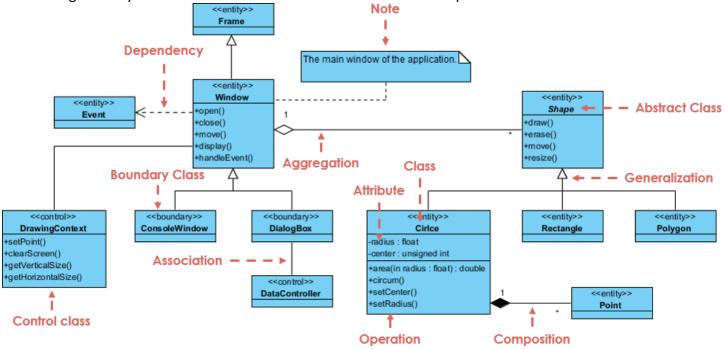

MyClass				
+attribute1 : int				
-attribute2 : float				
#attribute3 : Circle				
+op1(in p1 : bool, in p2) : String				
-op2(input p3 : int) : float				
#op3(out p6): Class6*				

	default	private	protected	public
Same Class	Yes	Yes	Yes	Yes
Same package subclass	Yes	No	Yes	Yes
Same package non- subclass	Yes	No	Yes	Yes
Different package subclass	No	No	Yes	Yes
Different package non- subclass	No	No	No	Yes

## **Class Diagram Example: GUI**

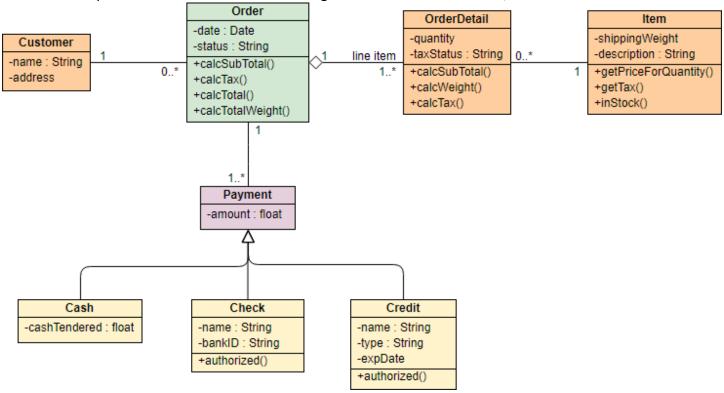

A class diagram may also have notes attached to classes or relationships.

## **UML Class Diagram Tutorial**

### What is a Class Diagram in UML?

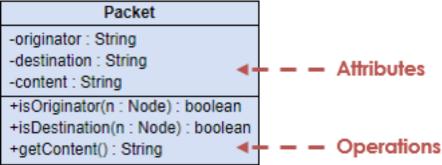

A class diagram describes the structure of an object-oriented system by showing the classes in that system and the relationships between the classes. A class diagram also shows constraints, and attributes of classes.

#### **Class Diagram Notations**

### Class

The UML representation of a class is a rectangle containing three compartments stacked vertically, as shown in the Figure:

### Attribute

The attribute section of a class lists each of the class's attributes on a separate line. The attribute section is optional, but when used it contains each attribute of the class displayed in a list format. The line uses this format: name: attribute type (e.g. cardNumber: Integer).

#### Operation

The operations are documented in the bottom compartment of the class diagram's rectangle, which also is optional. Like the attributes, the operations of a class are displayed in a list format, with each operation on its own line. Operations are documented using this notation: *name (parameter list)*: type of value returned (e.g. calculateTax (Country, State): Currency).

### Relationships

### Association

Some objects are made up of other objects. Association specifies a "has-a" or "whole/part" relationship between two classes. In an association relationship, an object of the whole class has objects of part class as instance data.

In a class diagram, an association relationship is rendered as a directed solid line.

**Unidirectional association** - In a unidirectional association, two classes are related, but only one class knows that the relationship exists.

A unidirectional association is drawn as a solid line with an open arrowhead pointing to the known class.

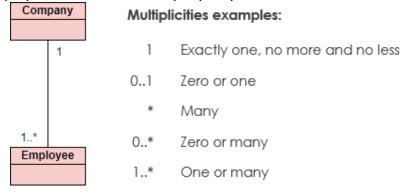

**Bidirectional (standard) association** - An association is a linkage between two classes. Associations are always assumed to be bi-directional; this means that both classes are aware of each other and their relationship, unless you qualify the association as some other type.

A bi-directional association is indicated by a solid line between the two classes.

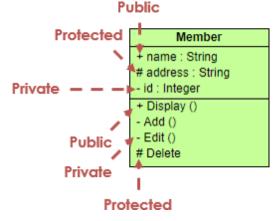

### Multiplicity

Place multiplicity notations near the ends of an association. These symbols indicate the number of instances of one class linked to one instance of the other class. For example, one company will have one or more employees, but each employee works for one company only.

### Visibility

Visibility is used to signify who can access the information contained within a class denoted with +, -, # and  $\cong$  as show in the figure:

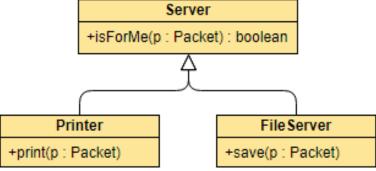

### Generalization

A generalization is a relationship between a general thing (called the superclass) and a more specific kind of that thing (called the subclass). Generalization is sometimes called an "is a kind of" relationship and is established through the process of inheritance.

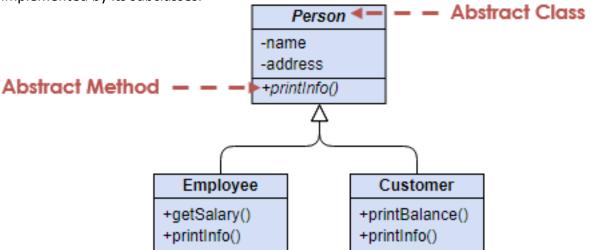

In a class diagram, generalization relationship is rendered as a solid directed line with a large open arrowhead

pointing to the parent class.

### **Abstract Classes and methods**

In an inheritance hierarchy, subclasses implement specific details, whereas the parent class defines the framework its subclasses. The parent class also serves a template for common methods that will be implemented by its subclasses.

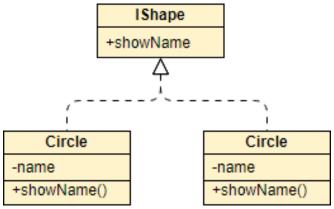

The name of an **abstract Class** is typically shown in italics; alternatively, an abstract Class may be shown using the textual annotation, also called stereotype {abstract} after or below its name.

An **abstract method** is a method that do not have implementation. In order to create an abstract method, create a operation and make it italic.

### Realization

A realization is a relationship between two things where one thing (an interface) specifies a contract that another thing (a class) guarantees to carry out by implementing the operations specified in that contract. In a class diagram, realization relationship is rendered as a dashed directed line with an open arrowhead pointing to the interface.

### Dependency

Dependency indicates a "uses" relationship between two classes. In a class diagram, a dependency relationship is rendered as a dashed directed line.

If a class A "uses" class B, then one or more of the following statements generally hold true:

- 1. Class B is used as the type of a local variable in one or more methods of class A.
- 2. Class B is used as the type of parameter for one or more methods of class A.
- 3. Class B is used as the return type for one or more methods of class A.
- 4. One or more methods of class A invoke one or more methods of class B.

#### **Associations**

Associations represent the *relationships* between classes. They are represented as a line connecting the two related classes, and at their simplest, that's all they are.

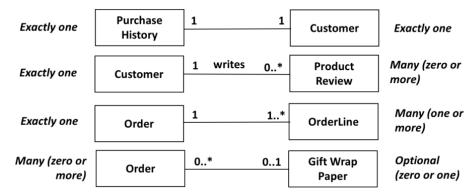

If the association has a navigability (i.e. an arrow on one end) it indicates that one class knows about the other but not vice versa. It's very handy to introduce navigabilities into your diagram as early as possible. If you're doing analysis, it will help you understand the responsibilities of each class and how they interact, and if you're doing design it'll help you think about the dependencies between your classes and the strength of their coupling.

You can give an association a name if it helps you understand the nature of the relationship. This will require some thought, though – something like *has* is not a good name! It'll help you more if you use something more descriptive.

If present, a small triangle next to the name shows you which direction to read the label. In this diagram, Students know about their Lecturer (i.e. each Student is keeping track of its associated Lecturer) but Lecturers don't know their Students. The little arrow next to the word *teaches* shows you that Lecturer teaches Student, not the other way around. Getting these notations, the wrong way around is a common mistake.

Each end of an association can has also show its *multiplicity*. This indicates how many objects of each class are involved in the association. For example:

You should steer clear of using variables in multiplicities, e.g. 0..N rather than 0..\* – it's not legal UML, and it can be confusing unless you make it very clear what those variables mean.

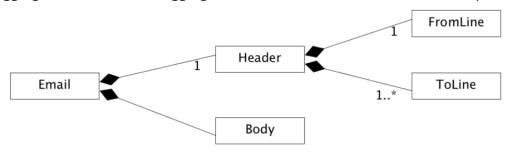

#### **Aggregate associations**

UML 2.4.1 defines two kinds of aggregate association: *composite aggregation* and *shared aggregation*. Composite aggregation is shown as a filled (black) diamond and shared aggregation is shown as an unfilled (white) diamond.

The UML 2.4.1 standard says that composite entities can't share members but aggregate entities can. That is, if an object is part of one composition, it can't be part of another. For the time being, we'll go with this definition – but as we'll see later, there's some controversy around it.

**Composite aggregation** often appears in software systems, because many composite objects appear in real life: a dog is a composite of a head, a body, a tail and four legs; an email is composed of a header and a text message; the header is composed of a From: line, a To: line, etc.

Composite aggregation is the kind of aggregation that exists between a whole and its parts.

The three most important characteristics of composite aggregation as opposed to shared aggregation are:

- the composite object does not exist without its components,
- at any time, each component may be part of only one composite, and
- component objects are *likely* to be of mixed types (although this isn't *always* the case.)

**Shared aggregation** is also a familiar concept from real life: a forest is an aggregate of trees, and a flock is an aggregate of sheep. It's so common that the word "aggregation", by itself, usually refers to shared aggregation.

An aggregation is the kind of association that exists between a group and its members.

The three most important characteristics of shared aggregation are:

- the aggregate object may potentially exist without its constituent objects (although not necessarily in a useful state),
- at any time, each object may be a constituent of more than one aggregate (e.g. a person may belong to several clubs), and
- constituent objects are typically of the same class (but, again, that's not always the case).

### **Constraints**

The elements of a class diagram (associations, attributes and generalisation, etc.) are effectively placing constraints on the system. For example, an association can indicate that an order must have a customer by having a multiplicity of 1 at the customer end. But sometimes, you'll need to specify constraints on the system that can't be covered by these structural elements.

In UML, you can simply write these constraints in natural language and place them inside curly brackets ({ }). At the conceptual level, it's best if you use simple statements, such as {ordered} to show that a particular collection must be ordered in some way.

You can apply these constraints to any part of the diagram: attributes, associations, classes, etc.

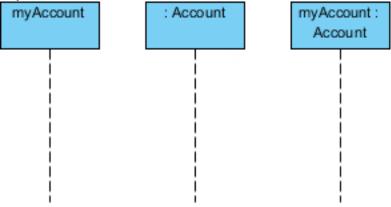

# **UML Sequence Diagrams Tutorial**

### Object

In the UML, an object in a sequence diagram is drawn as a rectangle containing the name of the object, underlined. An object can be named in one of three ways: the object name, the object name and its class, or just the class name (anonymous object). The three ways of naming an object are shown in Figure below.

#### Lifeline

Entities of participants in a collaboration (scenario) are written horizontally across the top of the diagram. A lifeline is represented by dashed vertical line drawn below each object. These indicate the existence of the object.

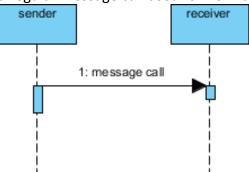

Object names can be specific (e.g., myAccount) or they can be general (e.g., myAccount :Account). Often, an anonymous object (:Account) may be used to represent any object in the class. Each object also has its timeline represented by a dashed line below the object. Messages between objects are represented by arrows that point from sender object to the receiver object.

Everything in an object-oriented system is accomplished by objects. Objects take on the responsibility for things like managing data, moving data around in the system, responding to inquiries, and protecting the system. Objects work together by communicating or interacting with one another.

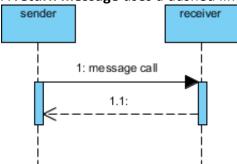

#### Message

Messages depict the invocation of operations are shown horizontally. They are drawn from the sender to the receiver. Ordering is indicated by vertical position, with the first message shown at the top of the diagram, and the last message shown at the bottom. As a result, sequence numbers is optional. The line type and arrowhead type indicates the type of message being used:

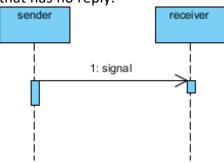

1. A **synchronous message** (typically an operation call) is shown as a solid line with a filled arrowhead. It is a regular message call used for normal communication between sender and receiver.

2. A **return message** uses a dashed line with an open arrowhead.

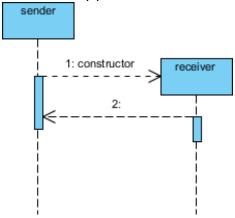

3. An **asynchronous message** has a solid line with an open arrowhead. A signal is an asynchronous message that has no reply.

### **Creation and Destruction Messages**

Participants do not necessarily live for the entire duration of a sequence diagram's interaction. Participants can be created and destroyed according to the messages that are being passed.

A **constructor message** creates its receiver. The sender that already exist at the start of the interaction are placed at the top of the diagram. Targets that are created during the interaction by a constructor call are automatically placed further down the diagram.

A **destructor message** destroys its receiver. There are other ways to indicate that a target is destroyed during an interaction. Only when a target's destruction is set to 'after destructor' do you have to use a destructor.

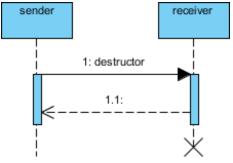

Figure 2. A sequence diagram that has incoming and outgoing messages

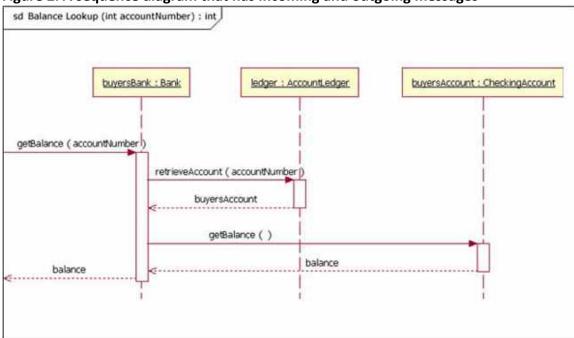

Figure 4. An example of messages being sent between objects

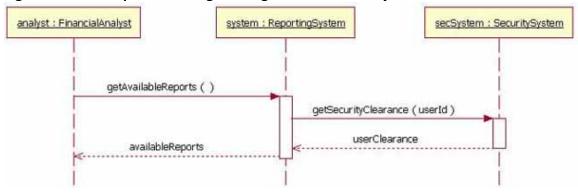

Figure 5. The system object calling its determineAvailableReports method

Figure 8. A sequence diagram fragment that contains an alternative combination fragment

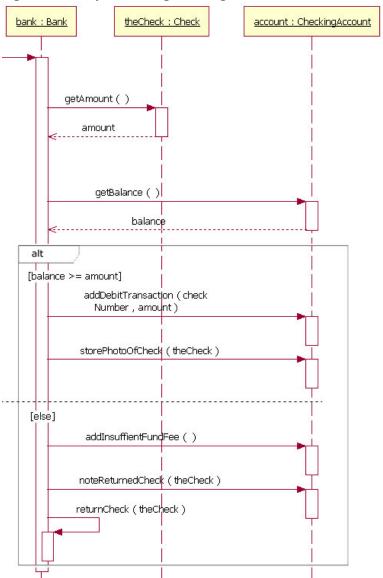

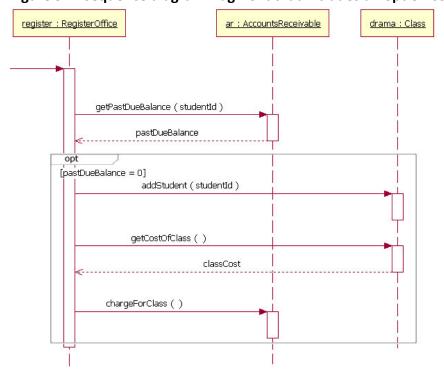

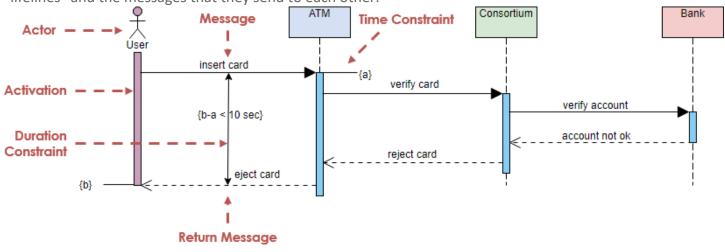

Figure 9. A sequence diagram fragment that includes an option combination fragment

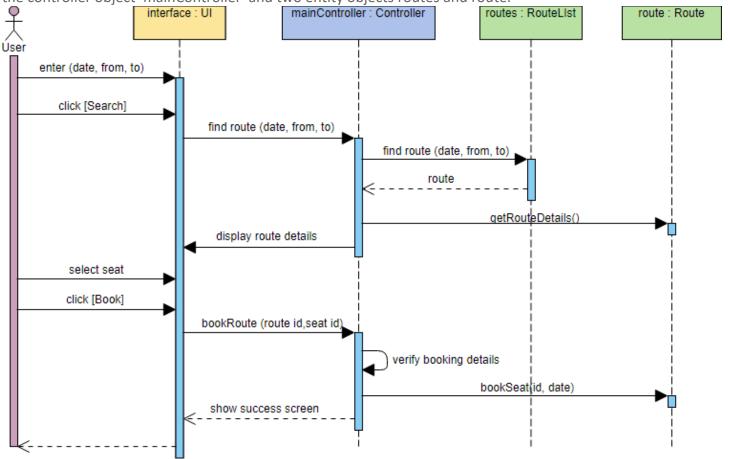

# **UML Sequence Diagram Tutorial**

A **sequence diagram** describes an interaction among a set of objects participated in a collaboration (or scenario), arranged in a chronological order; it shows the objects participating in the interaction by their "lifelines" and the messages that they send to each other.

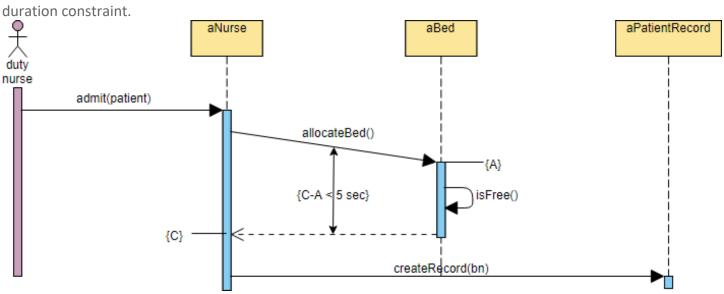

### **Sequence Diagram Examples**

The sequence diagram example below shows the interactions between a user and a ticket booking system in booking a seat. It consists of mainly four parts: The actor, which is the user, the boundary object 'interface', the controller object 'mainController' and two entity objects routes and route.

The sequence diagram example below shows a patient admission process. It shows the use of timing and

The sequence diagram example shows how recursive message can be used in interaction modeling.
